

Almost **everything** in Java is an **object**. Therefore, to do at least **one thing** in Java we need at least **one object**.

## What you need to run a Java program

|   |   |
|---|---|
| <ul style="list-style-type: none"> <li>We write <b>public class</b> followed by the class name</li> <li>Everything inside the first <b>curly braces</b> belongs to that class</li> <li>The class needs an action called <b>main</b> preceded with the keywords <b>public static void</b> followed by the arguments</li> <li>The <b>code</b> inside its curly braces will be <b>run</b></li> </ul> | <pre>public class IAmADeveloper {     public static void main(String[] args) {         System.out.println("I am a developer.");     } }</pre> |
|---|---|

Curly braces { } and semicolons ; are **everywhere** in Java. They express where things **start** and where they **end**. When we **define** something we use **curly braces**. When we **use** something we end the line with a **semicolon**.

## Variables

|  |  |
|--|--|
| <ul style="list-style-type: none"> <li><b>Boolean</b> and <b>String</b> stay the same</li> <li><b>Number</b> divides itself in several other number types</li> <li><b>Collections</b> stay almost the same but need a little bit more of explanation. We will use <b>List</b> instead</li> </ul> | <pre>Boolean isReady = true; isReady = false;  Integer size = 5; size = size + 7;  String name = "Mittens";  Collection&lt;String&gt; names = Arrays.asList("Paws", name); Collection&lt;Integer&gt; ages = new ArrayList&lt;&gt;();</pre> |
|--|--|

## Variable kinds

|   |   |
|---|---|
| <p>There are two variable kinds, <b>primitive</b> and <b>objects</b>:</p> <ul style="list-style-type: none"> <li>The difference is in <b>performance</b></li> <li><b>Primitives</b> use the memory as it is and offer <b>nothing</b> special</li> <li><b>Objects</b> require much more memory but offer plenty of <b>traits</b></li> <li>Primitives start with a <b>small</b> letter and Objects start with a <b>capital</b> one</li> </ul> | <pre>Boolean isReady = true; boolean isRegistered = false;  Integer size = 5; int age = 24;  String name = "Mittens"; char letter = 'a';  Collection&lt;Integer&gt; ages = new ArrayList&lt;&gt;(); String[] words = new String[5];</pre> |
|---|---|

## Variable type summary

| robocode types | Java types |
|----------------|------------|
|                |            |

|            |                                    |
|------------|------------------------------------|
| Number     | int and float<br>Integer and Float |
| String     | char<br>String                     |
| Boolean    | boolean<br>Boolean                 |
| Collection | array<br>List                      |

## Methods

|  |   |
|--|---|
| <ul style="list-style-type: none"> <li>Start with the <b>visibility</b> keyword</li> <li>Continue with the <b>return type</b>, <b>void</b> if it returns nothing</li> <li>Continue with the name</li> <li>Continue with the <b>arguments</b></li> <li><b>Definition</b> between curly braces</li> <li>If they return something (not <b>void</b>) the last line uses the <b>return</b> keyword</li> </ul> | <pre>public void askForHelp(String message, Integer times){     // says the emergency message that many times }  public String reverse(String word) {     String reversed = "";     // some more code goes here...     return reversed; }</pre> |
|--|---|

## Conditionals

|  |  |
|--|--|
| <p>They follow the next rules:</p> <ul style="list-style-type: none"> <li>Start with the <b>if</b> keyword</li> <li>Define the <b>condition</b> between <b>parentheses</b></li> <li><b>Code</b> related is written between <b>curly braces</b></li> <li>If <b>more logic</b> is necessary, it could continue with <b>else</b> or <b>else if</b></li> </ul> | <pre>if (isTimeToChange &amp;&amp; isWillingToChange) {     change(); } else if (isTimeToChange &amp;&amp; !isWillingToChange){     considerChanging(); } else {     dontChange(); }</pre> |
|--|--|

## Loops

|   |   |
|---|---|
| <p>There are several types of loops:</p> <ul style="list-style-type: none"> <li>Repeat for each</li> <li>Repeat an amount of times</li> <li>Repeat while</li> </ul> | <pre>for (String name : names) {     System.out.println(name); }  for (int times = 0; times &lt; 10; times++) {     System.out.println("Alan!"); }  while(!areWeThere()){     askAreWeThereYet(); }</pre> |
|---|---|

## How to say and listen in Java

- Instead of say and listen we will have to write on the screen and read from the keyboard
- The say version of Java is the `System.out.println()`
- The listen version of Java is handled by the class `Scanner`

```
System.out.println("Are you wearing a hat?");
```

```
Scanner scanner = new Scanner(System.in);
```

```
String answer = scanner.nextLine();
```
